

Sedative/Tranquilizers with Antispasmodics

It is believed (no evidence) that calming (slowing down) the brain and nerve signals will indirectly calm the gastrointestinal track (stomach and intestines) causing an antispasmodic effect There is no scientific evidence that exist to prove that this is true.

The AMA Drug Evaluation essentially states that sedatives and tranquilizers mixed with antispasmodics, is irrational (stupid) and do not recommend using them.

The drug combination interactions are undesired (wrong). Aside from this, the ingredients sometimes added such as barbiturates (a sedative) are addicting.

The long-term use causes addiction to the drug or the product Addiction to the product helps provide a steady income for the pharmaceutical (prescription) drug pushers.
